VLF scattering by *D*-region disturbances

Artificial *D*-region disturbances are caused by **HF heaters** or **VLF transmitters**. The ground VLF perturbations were calculated previously (using Earth-ionosphere waveguide mode theory both WKB and Born approximations):

- for HF heaters: *Barr et al* [1985]; *Demirkol* [Ph. D thesis, 1999]
- for VLF transmitters: *Inan et al* [1992]; *Rodriguez* [Ph. D thesis, 1994]

We use Stanford Full-Wave Method (SFWM), with Born approximation (but no WKB approximation).

Outline

1 Overview

2 Stanford Full-Wave Method (SFWM) code

- SFWM capabilities
- SFWM description

3 VLF scattering by an HF heater

- Waveguide modes
- Kinetic model results for Δv_e
- Scattering in Born approximation
- Scattered VLF wave (ΔA) on the ground
- Scattered VLF wave in the ionosphere

4 VLF scattering by a VLF transmitter heating

- VLF heating model
- SFWM results for scattered waves

5 Summary

Capabilities:

- Arbitrary **plane stratified** medium, e.g., a horizontally-stratified magnetized plasma with an arbitrary direction of geomagnetic field (such as ionosphere)
- Arbitrary configuration of harmonically varying currents
- Provides full wave 3D solution of both whistler waves launched into ionosphere and VLF waves launched into Earth-ionosphere waveguide
- Stable against the “swamping” instability by evanescent waves
- Efficient use of the computer resources, easily parallelized

Applications:

- Trans-ionospheric propagation
- Earth-ionosphere waveguide propagation
- Scattering on *D*-region disturbances

We work in Fourier (horizontal wave vector \mathbf{k}_\perp) domain:

- 1 For each $\mathbf{k}_\perp = \text{const}$ (Snell's law) \implies find k_z , E and H in each layer for each of 4 plane wave modes (2 up, 2 down)
- 2 Use continuity of \mathbf{E}_\perp and \mathbf{H}_\perp between layers to find reflection coefficients $R^{u,d}$ and mode amplitudes \mathbf{u} , \mathbf{d}
 - Recursion order $R_{k+1}^u \rightarrow R_k^u$ and $\mathbf{u}_k \rightarrow \mathbf{u}_{k+1}$ provides stability against "swamping" of solution by evanescent waves
 - Represent source currents as boundary conditions on \mathbf{E}_\perp and \mathbf{H}_\perp between layers
- 3 Inverse Fourier transform from \mathbf{k}_\perp to \mathbf{r}_\perp

NLK/HAARP

NLK VLF transmitter:

- Modelled as a ground-based vertical dipole
- $f = 24.8$ kHz
- $P = 250$ kW

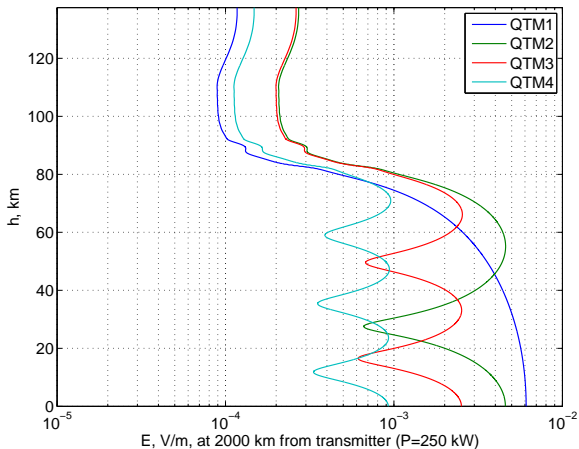

HAARP HF heater:

- $f_{\text{HF}} = 5$ MHz
- ERP = 1 GW
- Beam width ~ 23 km [Payne et al, 2007], we assume Gaussian horizontal shape
- ΔT_e and Δv_e are found using kinetic equations

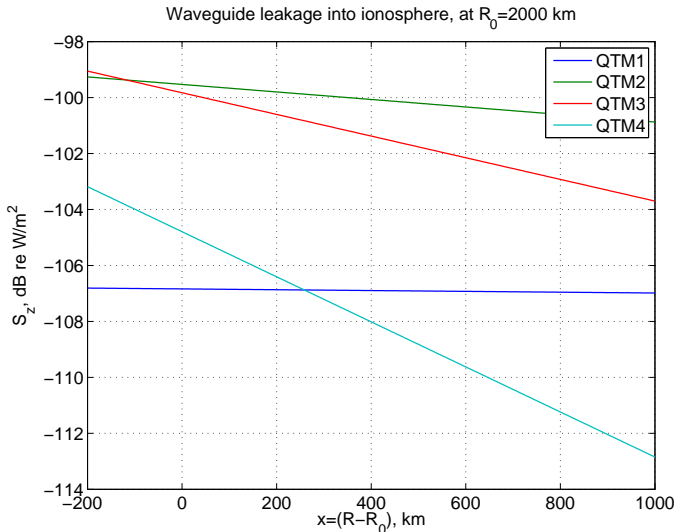

Strongest modes at $R_0 = 2000$ km (disturbance)

- Modes are calculated using SFWM using night-time ionosphere
- Attenuation is due to both **absorption** and **radiation into ionosphere**

Waveguide radiation leaking into ionosphere

Role of whistler radiation in the total attenuation

Change in v_e due to heating

Steady heating; the heater is turned on at $t = 0$

We must solve the wave equation:

$$\nabla \times (\nabla \times \mathbf{E}) - k_0^2 \hat{\epsilon} \mathbf{E} = 0 \quad (k_0 = \omega/c)$$

where $\mathbf{E} = \mathbf{E}_0 + \mathbf{E}_s$, $\hat{\epsilon} = \hat{\epsilon}_0 + \Delta\hat{\epsilon}$,

- \mathbf{E}_0 — incoming wave (e.g., a waveguide mode in stratified $\hat{\epsilon}_0$);
- \mathbf{E}_s — scattered wave;
- $\Delta\hat{\epsilon}$ — inhomogeneous change in the dielectric permittivity tensor.

In a stratified waveguide $\nabla \times (\nabla \times \mathbf{E}_0) - k_0^2 \hat{\epsilon}_0 \mathbf{E}_0 = 0 \quad \implies$

$$\nabla \times (\nabla \times \mathbf{E}_s) - k_0^2 \hat{\epsilon}_0 \mathbf{E}_s = k_0^2 \Delta\hat{\epsilon} (\mathbf{E}_0 + \mathbf{E}_s)$$

- **Born approximation**: neglect \mathbf{E}_s compared to \mathbf{E}_0 inside the scattering region (rhs).
- rhs gives the source currents for scattered waves:

$$\nabla \times (\nabla \times \mathbf{E}_s) - k_0^2 \hat{\epsilon}_0 \mathbf{E}_s \approx k_0^2 \Delta\hat{\epsilon} \mathbf{E}_0 = ik_0 Z_0 \Delta\mathbf{J}$$

where Z_0 is the impedance of free space.

- VLF wave propagates from left to right ($x = R - R_0$)
- scattering region is indicated by a circle at $x = 0, y = 0$

QTM1 mode

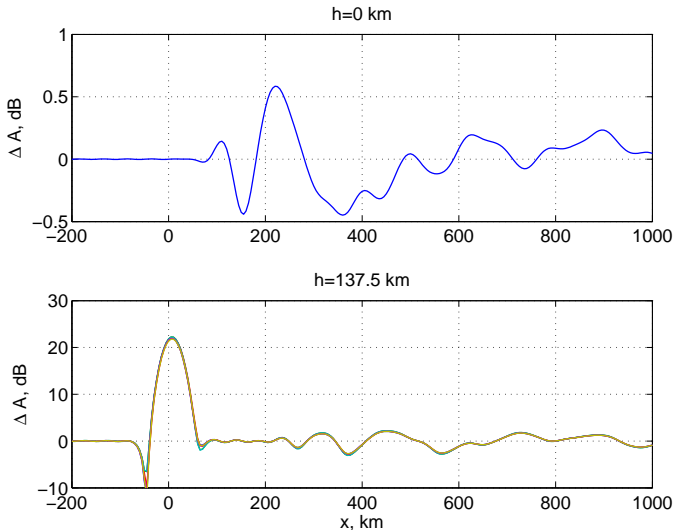

QTM2 mode

ΔA on the ground and in space: QTM1 mode

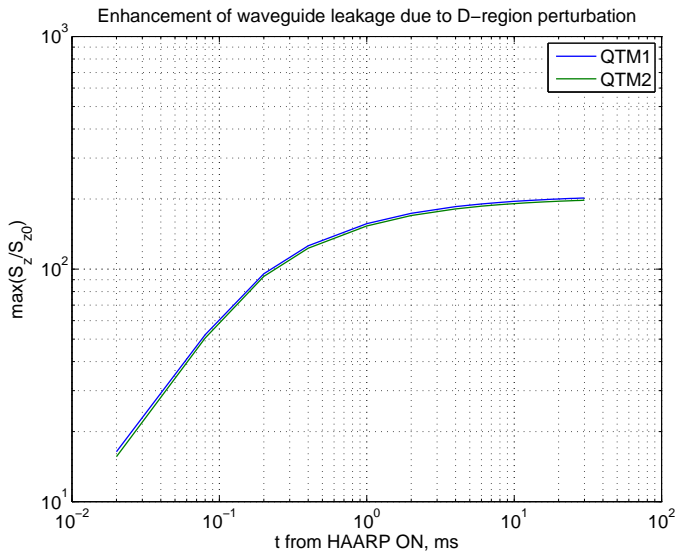

ΔA on the ground and in space: QTM2 mode

The flux scattered by the heated region upward significantly exceeds the waveguide leakage

Whistler flux scattered into space ($h = 137.5$ km)

- intense “column”
- weaker “tail” in the shadow of the scatterer

Results are shown for **QTM1** mode (other modes are similar)

NAA/NAU (chosen after *Inan et al* [1992])

NAA VLF transmitter:

- $f = 24$ kHz
- $P = 1000$ kW

NAU VLF transmitter as a heater:

- $f = 40.75$ kHz
- $P = 100$ kW
- ΔT_e and Δv_e are found using SFWM and a model presented on the next slide

PA is the VLF receiver at Palmer station, Antarctica

VLF heating model

T_e is obtained from the temperature balance due to E -field heating and cooling due to collisions:

$$T_e = T_0 + \frac{2U}{3\delta\nu_e N_e k_B}$$

where

- $\delta\nu_e$ is the energy loss rate, with $\delta \approx 1.3 \times 10^{-3}$ being the fraction of electron energy lost in a collision with a molecule [*Inan et al*, 1992]. Note that ν_e is the *momentum* loss rate;
- $U = \frac{1}{2} \Re(\mathbf{J}^* \cdot \mathbf{E})$ is the absorbed VLF wave power;
- $\mathbf{J} = \hat{\sigma} \mathbf{E}$, with anisotropic $\hat{\sigma}$
- \mathbf{E} is calculated in the vicinity of the transmitter using the (linear) SFWM model.
- $\nu_e = (T_e/T_0)\nu_{e0}$ is the heated collision frequency, ν_{e0} is the background collision frequency [*Inan et al*, 1992].

$$\Delta T_e$$

- VLF propagation is from left to right
- White arrow indicates (downward) \mathbf{B}
- The “hole” in the middle is due to dipole radiation pattern
- At $h = 82$ km, more heating at $x < 0$ because the electrons are heated better when $\mathbf{E} \parallel \mathbf{B}$
- At $h = 92$ km, more heating at $x > 0$ because whistlers propagate more favorably along \mathbf{B}

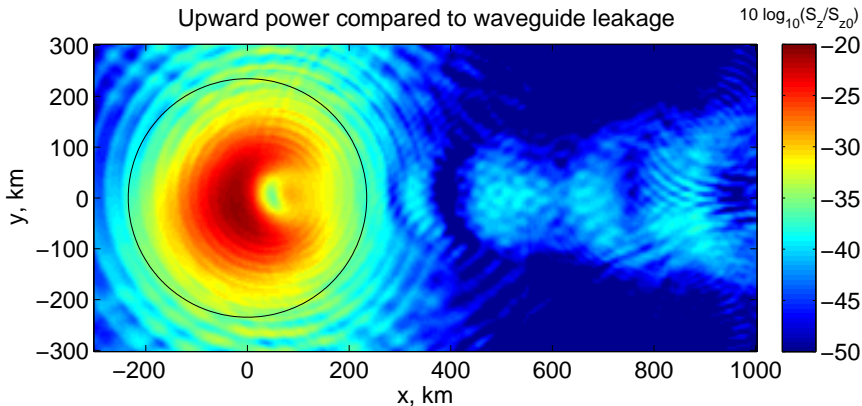

VLF perturbation on the ground

Experimental value: ± 0.03 – 0.12 dB [*Inan et al*, 1992]

Scattered whistlers in ionosphere

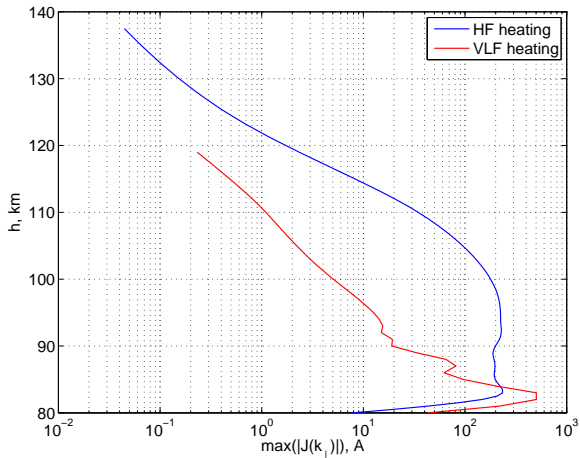

Notice that the upward-scatter power flux is negligible compared to waveguide leakage.

Why such a difference in upward scattering?

The VLF heating occurred at lower altitudes, and therefore was more attenuated.

Outline

- 1 Overview
- 2 Stanford Full-Wave Method (SFWM) code
 - SFWM capabilities
 - SFWM description
- 3 VLF scattering by an HF heater
 - Waveguide modes
 - Kinetic model results for Δv_e
 - Scattering in Born approximation
 - Scattered VLF wave (ΔA) on the ground
 - Scattered VLF wave in the ionosphere
- 4 VLF scattering by a VLF transmitter heating
 - VLF heating model
 - SFWM results for scattered waves
- 5 Summary

Summary:

- Stanford Full-Wave Method (SFWM) was applied to calculate Earth-ionosphere waveguide modes and their scattering on *D*-region disturbances
- The scattered waves are emitted both into the Earth-ionosphere waveguide and into the ionosphere
- Whistler waves scattered into the ionosphere form an intense “column” and a weaker “tail” in the shadow of the scatterer
- VLF enhancements inside the whistler “column” may significantly exceed the background leakage from the Earth-ionosphere waveguide
- *D*-region disturbances may contribute to the electromagnetic radiation environment in the ionosphere and magnetosphere

To do:

- Include VLF perturbations due to change in N_e (longer timescale, due to change in attachment coefficient)
- Kinetic model of VLF heating
- Experimental verification
